### Naive Bayes

The model assumes a probabilistic data distribution:

- categorical and continues features
- categorical: multinomial or Bernoulli (binary featues)
- continues: Gaussian
- makes a strong assumption: features are independent given the label.
- generative model P(x|y)

July 6, 2020 6 / 61

### Problem 5

Suppose you are given the following set of data with three Boolean input variables a, b, and c, and a single Boolean output variable K.

a	b	c	K
1	0	1	1
1	1	1	1
0	1	1	0
1	1	0	0
1	0	1	0
0	0	0	1
0	0	0	1
0	0	1	0

According to the naive Bayes classifier, what is a value of P(K = 1|a = 1,b = 1,c = 0)?

Example No.	Color	Type	Origin	Stolen?
1	Red	Sports	Domestic	Yes
2	Red	Sports	Domestic	No
3	Red	Sports	Domestic	Yes
4	Yellow	Sports	Domestic	No
5	Yellow	Sports	Imported	Yes
6	Yellow	ŜUV	Imported	No
7	Yellow	SUV	Imported	Yes
8	Yellow	SUV	Domestic	No
9	Red	SUV	<b>Imported</b>	No
10	Red	Sports	Imported	Yes

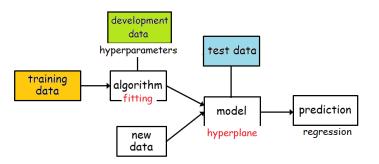

Given training examples above, classify a Red Domestic SUV.

#### Linear Regression

Reading: Bishop chapters 3.1, 4.1, 4.3, 7.1; ESL chapter 3

July 6, 2020 9 / 61

#### Classification

Classification is a problem of finding a mapping function f from training data  $(x \in \mathbb{R}^D)$  to *discrete* output variables  $(y \in C)$ .

- The output variables are called labels or classes or categories.
- The mapping function predicts the class for a given observation.
- The classification *accuracy* is computed as the percentage of correctly classified examples out of all examples.

#### Predictive modeling

Predictive modeling (i.e. supervised learning) is a process of creating a model using data to make a prediction on new data.

Predictive modeling is a problem of finding a mapping function f from training data  $(x \in \mathbb{R}^D)$  to output variables.

There are important differences between classification and regression problems.

- continuous vs discrete
- measure *prediction errors* differently.
- lead to quite different learning algorithms.

July 6, 2020 10 / 61

### Regression

Regression is a problem of finding a mapping function f from training data  $(x \in \mathbb{R}^D)$  to a *continuous* output variable  $(y \in \mathbb{R})$ .

- The output variable is a continuous quantity; pricing optimization, sales forecasting, rating forecasting are some examples.
- Regression predictions can be evaluated using the *mean squared error*.

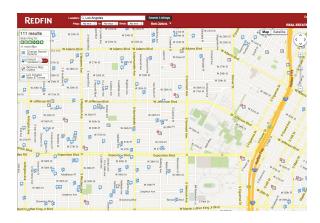

In some cases, a classification problem can be converted to a regression problem. Some algorithms do this by predicting a probability for each class.

**Linear Regression:** regression with linear models.

July 6, 2020 11 / 61 July 6, 2020 12

### Ex: Predicting the sale price of a house

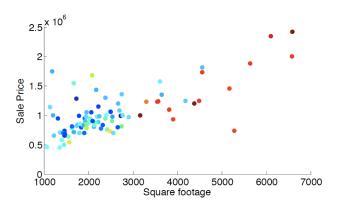

#### Retrieve historical sales records (training data)

July 6, 2020 13 / 61 July 6, 2020

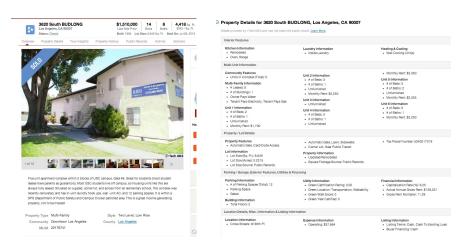

#### •

## Correlation between square footage and sale price

In linear regression, the goal is to predict  $\boldsymbol{y}$  from  $\boldsymbol{x}$  using a linear function.

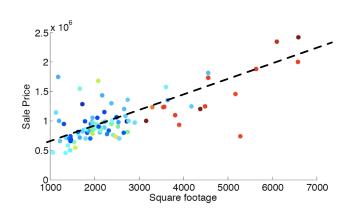

### Features used to predict

14 / 61

### Possibly linear relationship

Sale price  $\approx$  price\_per\_sqft  $\times$  square\_footage + fixed\_expense (slope) (intercept)

July 6, 2020 15 / 61 July 6, 2020 16 / 6

### How to learn the unknown parameters?

#### How to measure error for one prediction?

- The classification error (0-1 loss, i.e. *right* or *wrong*) is *inappropriate* for continuous outcomes.
- We can look at
  - absolute error: | prediction sale price |
  - ▶ or *squared* error: (prediction sale price)<sup>2</sup> (most common)

Goal: pick the model (unknown parameters) that minimizes the average/total prediction error, but *on what set*?

- test set, ideal but we cannot use test set while training
- training set? (minimize the training error)

July 6, 2020 17 / 61

### Formal setup for linear regression

**Input**:  $\boldsymbol{x} \in \mathbb{R}^{\mathsf{D}}$  (features, covariates, context, predictors, etc)

**Output**:  $y \in \mathbb{R}$  (responses, targets, outcomes, etc)

**Training data**:  $\mathcal{D} = \{(x_n, y_n), n = 1, 2, ..., N\}$ 

Here  $x_{nd}$  represents the dth dimension of the nth sample  $oldsymbol{x}_n$ 

**Linear model**:  $f: \mathbb{R}^{D} \to \mathbb{R}$ , with  $f(x) = w_0 + \sum_{d=1}^{D} w_d x_d$ 

Linear regression has been around for more than 200 years...

#### Example

Predicted price =  $price_per_sqft \times square_footage + fixed_expense$ one model:  $price_per_sqft = 0.3K$ ,  $fixed_expense = 210K$ 

sqft	sale price (K)	prediction (K)	squared error
2000	810	810	0
2100	907	840	$67^2$
1100	312	540	$228^{2}$
5500	2,600	1,860	$740^2$
		•••	
Total			$0 + 67^2 + 228^2 + 740^2 + \cdots$

Adjust **price\_per\_sqft** and **fixed\_expense** such that the total squared error is minimized.

July 6, 2020 18

#### Notation Convenience

NOTE: for notation convenience, we will

- ullet append 1 to each  $oldsymbol{x}_n$  as the first feature:  $oldsymbol{x} = [1, \ x_1, \ x_2, \ \dots, \ x_{\mathsf{D}}]^{\mathsf{T}}$
- append  $w_0$  to weights:  $\mathbf{w} = [w_0, w_1, w_2, \dots, w_D]^T$

The model becomes

$$f: \mathbb{R}^{\mathsf{D}+1} \to \mathbb{R}$$

$$f(\boldsymbol{x}) = \boldsymbol{w}^{\mathrm{T}} \boldsymbol{x} = \boldsymbol{x}^{\mathrm{T}} \boldsymbol{w}$$

So please pay attention to notations!

#### Goal

Minimize total squared error

ullet Residual Sum of Squares (RSS), a function of w

$$RSS(\boldsymbol{w}) = \sum_{n=1}^{N} (f(\boldsymbol{x}_n) - y_n)^2 = \sum_{n=1}^{N} (\boldsymbol{x}_n^{\mathrm{T}} \boldsymbol{w} - y_n)^2$$

- $oldsymbol{oldsymbol{w}}$  find  $oldsymbol{w}^* = \operatorname*{argmin}_{oldsymbol{w} \in \mathbb{R}^{\mathsf{D}+1}} \mathrm{RSS}(oldsymbol{w})$
- minimize the Euclidean distance, or find the least squares solution
- reduce machine learning to optimization

July 6, 2020 21 / 61

### Warm-up: D = 0

#### Optimization objective becomes

$$RSS(w_0) = \sum_{n=1}^{N} (w_0 - y_n)^2$$

$$\frac{\partial RSS(w_0)}{\partial w_0} = 2\sum_{n=1}^{N} (w_0 - y_n) = 0$$

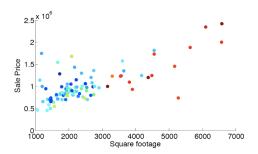

$$N w_0 - \sum_{n=1}^N y_n = 0$$

It follows that  $w_0 = \frac{1}{N} \sum_n y_n$ , i.e. the <code>average</code>

Exercise: what if we use absolute error instead of squared error?

### Warm-up: D = 0

Only one parameter  $w_0$ : constant prediction  $f(x) = w_0$ 

f is a horizontal line, where should it be?

Use calculus to find the value of  $w_0$  that minimizes the RSS

July 6, 2020 22/61

### Warm-up: D = 1

#### **Optimization objective becomes**

$$RSS(\boldsymbol{w}) = \sum_{n} (w_0 + w_1 x_n - y_n)^2$$

General approach: find stationary points, i.e., points with zero gradient

$$\begin{cases} \frac{\partial RSS(\boldsymbol{w})}{\partial w_0} = 0 \\ \frac{\partial RSS(\boldsymbol{w})}{\partial w_1} = 0 \end{cases} \Rightarrow \begin{array}{l} \sum_n (w_0 + w_1 x_n - y_n) = 0 \\ \sum_n (w_0 + w_1 x_n - y_n) x_n = 0 \end{cases}$$

$$\Rightarrow \begin{array}{ll} Nw_0 + w_1 \sum_n x_n &= \sum_n y_n \\ w_0 \sum_n x_n + w_1 \sum_n x_n^2 &= \sum_n y_n x_n \end{array} \quad \text{(a linear system)}$$

$$\Rightarrow \left(\begin{array}{cc} N & \sum_{n} x_{n} \\ \sum_{n} x_{n} & \sum_{n} x_{n}^{2} \end{array}\right) \left(\begin{array}{c} w_{0} \\ w_{1} \end{array}\right) = \left(\begin{array}{c} \sum_{n} y_{n} \\ \sum_{n} x_{n} y_{n} \end{array}\right)$$

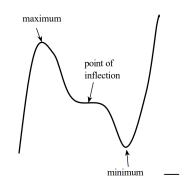

### Least square solution for $\mathsf{D}=1$

Assuming the matrix is invertible:

$$\Rightarrow \left(\begin{array}{c} w_0^* \\ w_1^* \end{array}\right) = \left(\begin{array}{cc} N & \sum_n x_n \\ \sum_n x_n & \sum_n x_n^2 \end{array}\right)^{-1} \left(\begin{array}{c} \sum_n y_n \\ \sum_n x_n y_n \end{array}\right)$$

#### Are stationary points minimizers?

- not true in general
- yes for convex objectives

July 6, 2020 25 / 61

#### General least square solution

#### **Objective**

$$RSS(\boldsymbol{w}) = \sum_{n} (\boldsymbol{x}_{n}^{\mathrm{T}} \boldsymbol{w} - y_{n})^{2}$$

Again, find stationary points (multivariate calculus)

$$\frac{1}{2}\nabla RSS(\boldsymbol{w}) = \sum_{n} \boldsymbol{x}_{n}(\boldsymbol{x}_{n}^{T}\boldsymbol{w} - y_{n}) = \left(\sum_{n} \boldsymbol{x}_{n}\boldsymbol{x}_{n}^{T}\right)\boldsymbol{w} - \sum_{n} \boldsymbol{x}_{n}y_{n}$$
$$= (\boldsymbol{X}^{T}\boldsymbol{X})\boldsymbol{w} - \boldsymbol{X}^{T}\boldsymbol{y} = \boldsymbol{0}$$

where

$$oldsymbol{X} = \left(egin{array}{c} oldsymbol{x}_1^{
m T} \ oldsymbol{x}_2^{
m T} \ dots \ oldsymbol{x}_{
m N}^{
m T} \end{array}
ight) \in \mathbb{R}^{{\sf N} imes (D+1)}, \quad oldsymbol{y} = \left(egin{array}{c} y_1 \ y_2 \ dots \ y_{
m N} \end{array}
ight) \in \mathbb{R}^{{\sf N}}$$

luly 6, 2020 26 /

#### General least square solution

#### $(\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})\boldsymbol{w} - \boldsymbol{X}^{\mathrm{T}}\boldsymbol{u} = \boldsymbol{0} \quad \Rightarrow \quad \boldsymbol{w}^* = (\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})^{-1}\boldsymbol{X}^{\mathrm{T}}\boldsymbol{u}$

assuming  $X^TX$  (called a covariance matrix) is invertible for now.

Again by convexity  $w^*$  is the minimizer of RSS.

#### Verify the solution when D = 1:

$$\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X} = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ x_1 & x_2 & \cdots & x_{\mathsf{N}} \end{pmatrix} \begin{pmatrix} 1 & x_1 \\ 1 & x_2 \\ \cdots & \cdots \\ 1 & x_{\mathsf{N}} \end{pmatrix} = \begin{pmatrix} N & \sum_n x_n \\ \sum_n x_n & \sum_n x_n^2 \end{pmatrix}$$

when D = 0:  $(\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})^{-1} = \frac{1}{N}$ ,  $\boldsymbol{X}^{\mathrm{T}}\boldsymbol{y} = \sum_{n} y_{n}$ 

### Another approach

#### RSS is the Euclidean norm squared:

$$RSS(\boldsymbol{w}) = \sum_{n} (\boldsymbol{w}^{T} \boldsymbol{x}_{n} - y_{n})^{2} = \|\boldsymbol{X} \boldsymbol{w} - \boldsymbol{y}\|_{2}^{2}$$

$$= (\boldsymbol{X} \boldsymbol{w} - \boldsymbol{y})^{T} (\boldsymbol{X} \boldsymbol{w} - \boldsymbol{y})$$

$$= (\boldsymbol{w}^{T} \boldsymbol{X}^{T} - \boldsymbol{y}^{T}) (\boldsymbol{X} \boldsymbol{w} - \boldsymbol{y})$$

$$= \boldsymbol{y}^{T} \boldsymbol{y} - \boldsymbol{y}^{T} \boldsymbol{X} \boldsymbol{w} - \boldsymbol{w}^{T} \boldsymbol{X}^{T} \boldsymbol{y} + \boldsymbol{w}^{T} \boldsymbol{X}^{T} \boldsymbol{X} \boldsymbol{w}$$

$$= \boldsymbol{y}^{T} \boldsymbol{y} - 2 \boldsymbol{y}^{T} \boldsymbol{X} \boldsymbol{w} + \boldsymbol{w}^{T} \boldsymbol{X}^{T} \boldsymbol{X} \boldsymbol{w}$$

Note: 
$$\mathbf{y}^{\mathrm{T}} \mathbf{X} \mathbf{w} = (\mathbf{w}^{\mathrm{T}} \mathbf{X}^{\mathrm{T}} \mathbf{y})^{\mathrm{T}}$$

#### Multivariate Calculus

#### RSS is given by

$$RSS(\boldsymbol{w}) = \boldsymbol{y}^{\mathrm{T}} \boldsymbol{y} - 2 \boldsymbol{y}^{\mathrm{T}} \boldsymbol{X} \boldsymbol{w} + \boldsymbol{w}^{\mathrm{T}} \boldsymbol{X}^{\mathrm{T}} \boldsymbol{X} \boldsymbol{w}$$

$$\nabla \text{RSS}(\boldsymbol{w}) = \nabla \left( \boldsymbol{y}^{\text{T}} \boldsymbol{y} - 2 \boldsymbol{y}^{\text{T}} \boldsymbol{X} \boldsymbol{w} + \boldsymbol{w}^{\text{T}} \boldsymbol{X}^{\text{T}} \boldsymbol{X} \boldsymbol{w} \right)$$

$$= 0 - 2 \boldsymbol{X}^{\text{T}} \boldsymbol{y} + \nabla \left( \boldsymbol{w}^{\text{T}} \boldsymbol{X}^{\text{T}} \boldsymbol{X} \boldsymbol{w} \right)$$

$$= -2 \boldsymbol{X}^{\text{T}} \boldsymbol{y} + 2 \boldsymbol{X}^{\text{T}} \boldsymbol{X} \boldsymbol{w} \qquad (prove it !)$$

It follows

$$(\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})\boldsymbol{w} - \boldsymbol{X}^{\mathrm{T}}\boldsymbol{y} = \boldsymbol{0} \quad \Rightarrow \quad \boldsymbol{w}^* = (\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})^{-1}\boldsymbol{X}^{\mathrm{T}}\boldsymbol{y}$$

July 6, 2020 29 / 61

### Computational complexity

#### **Bottleneck** of computing

$$\boldsymbol{w}^* = \left( \boldsymbol{X}^{\mathrm{T}} \boldsymbol{X} \right)^{-1} \boldsymbol{X}^{\mathrm{T}} \boldsymbol{y}$$

is to invert the matrix  ${m X}^{\rm T}{m X} \in \mathbb{R}^{({\sf D}+1) imes ({\sf D}+1)}$ 

- naively need  $O(\mathsf{D}^3)$  time
- there are many faster approaches (such as gradient descent)

#### Multivariate Calculus

#### Is it a minimizer?

$$\boldsymbol{w}^* = (\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})^{-1}\boldsymbol{X}^{\mathrm{T}}\boldsymbol{y}$$

We will use a second derivative (the Hessian matrix)

$$\nabla^2 \text{RSS}(\boldsymbol{w}) = \nabla \left( -2\boldsymbol{X}^{\mathrm{T}}\boldsymbol{y} + 2\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X}\boldsymbol{w} \right) = 2\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X}$$

A symmetric matrix M is said to be a **positive semi-definite** (PSD) if  $u^{T}Mu \geq 0$  for any vector u.

Note: 
$$u^{\mathrm{T}}(\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})u = (\boldsymbol{X}u)^{\mathrm{T}}\boldsymbol{X}u = \|\boldsymbol{X}u\|_2^2 \geq 0$$
 and is  $0$  if  $u = 0$ .

The Hessian matrix of a convex function is positive semi-definite.

July 6, 2020 30

### What if $\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X}$ is not invertible

#### Why would that happen?

One situation:  ${\sf N} < {\sf D}+1$ , i.e. not enough data to estimate all parameters.

#### **Example:** D = N = 1

sqft	sale price
1000	500K

Any line passing through this single point is a minimizer of RSS.

### How about the following?

#### D = 1, N = 2

sqft	sale price
1000	500K
1000	600K

Any line passing the average is a minimizer of RSS.

$$D = 2, N = 3$$
?

sqft	#bedroom	sale price
1000	2	500K
1500	3	700K
2000	4	800K

Again *infinitely many minimizers*. How to resolve this issue?

July 6, 2020 33 / 61

#### Eigendecomposition

The decomposition of a square matrix A into matrices composed of its eigenvectors and eigenvalues is called eigendecomposition.

$$A = U\Lambda U^{-1}$$

where  $\Lambda$  is a diagonal matrix of eigenvalues of A, and each column of U is an eigenvector of A.

If A is symmetric  $U^{\mathrm{T}}U = I$ , then

$$A = U\Lambda U^{-1} = U\Lambda U^{\mathrm{T}} = U^{\mathrm{T}}\Lambda U$$

and its inverse

$$A^{-1} = U^{\mathrm{T}} \Lambda^{-1} U$$

July 6, 2020 34 /

#### How to resolve this issue?

#### **Eigendecomposition**:

$$m{X}^{\mathrm{T}}m{X} = m{U}^{\mathrm{T}} egin{bmatrix} \lambda_1 & 0 & \cdots & 0 \ 0 & \lambda_2 & \cdots & 0 \ dots & dots & dots & dots \ 0 & \cdots & \lambda_{\mathsf{D}} & 0 \ 0 & \cdots & 0 & \lambda_{\mathsf{D}+1} \end{bmatrix} m{U}$$

where  $\lambda_1 \geq \lambda_2 \geq \cdots \lambda_{D+1} \geq 0$  are **eigenvalues**.

Inverse:

$$(\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})^{-1} = \boldsymbol{U}^{\mathrm{T}} \begin{bmatrix} \frac{1}{\lambda_{1}} & 0 & \cdots & 0 \\ 0 & \frac{1}{\lambda_{2}} & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \frac{1}{\lambda_{\mathrm{D}}} & 0 \\ 0 & \cdots & 0 & \frac{1}{\lambda_{\mathrm{D}+1}} \end{bmatrix} \boldsymbol{U}$$

### How to solve this problem?

Non-invertible  $\Rightarrow$  some eigenvalues are 0.

One natural fix: add something positive

$$\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X} + \lambda \boldsymbol{I} = \boldsymbol{U}^{\mathrm{T}} \begin{bmatrix} \lambda_{1} + \lambda & 0 & \cdots & 0 \\ 0 & \lambda_{2} + \lambda & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \lambda_{\mathsf{D}} + \lambda & 0 \\ 0 & \cdots & 0 & \lambda_{\mathsf{D}+1} + \lambda \end{bmatrix} \boldsymbol{U}$$

where  $\lambda > 0$  and  $\boldsymbol{I}$  is the identity matrix. Now it is invertible:

$$(\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X} + \lambda \boldsymbol{I})^{-1} = \boldsymbol{U}^{\mathrm{T}} \begin{bmatrix} \frac{1}{\lambda_{1} + \lambda} & 0 & \cdots & 0 \\ 0 & \frac{1}{\lambda_{2} + \lambda} & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \frac{1}{\lambda_{D} + \lambda} & 0 \\ 0 & \cdots & 0 & \frac{1}{\lambda_{D+1} + \lambda} \end{bmatrix} \boldsymbol{U}$$

#### Solution

The solution becomes

$$\boldsymbol{w}^* = \left( \boldsymbol{X}^{\mathrm{T}} \boldsymbol{X} + \lambda \boldsymbol{I} \right)^{-1} \boldsymbol{X}^{\mathrm{T}} \boldsymbol{y}$$

• not a minimizer of the original RSS

 $\lambda$  is a *hyper-parameter*, can be tuned by cross-validation.

How do we predict?

$$f(\boldsymbol{x}) = {\boldsymbol{w}^*}^{\mathrm{T}} \boldsymbol{x}$$

July 6, 2020 37 / 61

### Comparison to NNC

Parametric versus non-parametric

- Parametric methods: the size of the model does *not grow* with the size of the training set N.
  - e.g. linear regression, Naive Bayes
- Non-parametric methods: the size of the model *grows* with the size of the training set.
  - ▶ NNC, Decision Trees

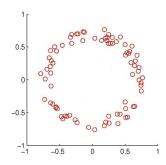

July 6, 2020 38 / 61

#### Outline

- Review
- Problem Solving
- 3 Linear regression
- 4 Linear regression with nonlinear basis
- 5 Overfitting and Preventing Overfitting
- 6 Problem Solving

### What if linear model is not a good fit?

Example: a straight line is a bad fit for the following data

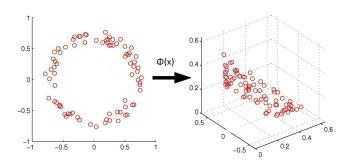

### Solution: nonlinearly transformed features

#### 1. Use a nonlinear mapping

$$oldsymbol{\phi}(oldsymbol{x}):oldsymbol{x}\in\mathbb{R}^D
ightarrowoldsymbol{z}\in\mathbb{R}^M$$

to transform the data to a more complicated feature space

**2.** Then apply linear regression (hope: linear model is a better fit for the new feature space).

July 6, 2020 41 / 61

#### Regression with nonlinear basis

Model:  $f(\boldsymbol{x}) = \boldsymbol{w}^{\mathrm{T}} \boldsymbol{\phi}(\boldsymbol{x})$  where  $\boldsymbol{w} \in \mathbb{R}^{M}$ 

#### **Objective:**

$$RSS(\boldsymbol{w}) = \sum_{n} (\boldsymbol{w}^{\mathrm{T}} \boldsymbol{\phi}(\boldsymbol{x}_{n}) - y_{n})^{2}$$

#### Similar least square solution:

$$m{w}^* = \left(m{\Phi}^{\mathrm{T}}m{\Phi}
ight)^{-1}m{\Phi}^{\mathrm{T}}m{y} \quad ext{where} \quad m{\Phi} = \left(egin{array}{c} m{\phi}(m{x}_1)^{\mathrm{T}} \ m{\phi}(m{x}_2)^{\mathrm{T}} \ dots \ m{\phi}(m{x}_N)^{\mathrm{T}} \end{array}
ight) \in \mathbb{R}^{N imes M}$$

July 6, 2020 42 / 61

#### Example

#### Polynomial basis functions for D=1

$$\phi(x) = \begin{bmatrix} 1 \\ x \\ x^2 \\ \vdots \\ x^M \end{bmatrix} \quad \Rightarrow \quad f(x) = w_0 + \sum_{m=1}^M w_m x^m$$

#### General case:

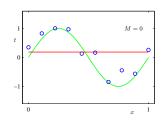

$$\phi(x) = \left[\prod_{i=1}^D x_i^{a_i} \right]$$
 , s.t.  $\sum_{i=1}^D a_i \leq M$ 

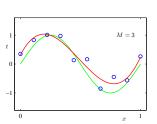

Learning a linear model in the new space

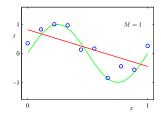

= learning an M-degree polynomial model in the original space

### Example

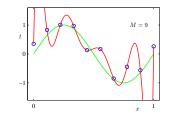

#### Fitting a sine function with a polynomial (M = 0, 1, or 3):

**M=9**: overfitting

### Why nonlinear?

Can I use a fancy linear feature map? For example,

$$oldsymbol{\phi}(oldsymbol{x}) = \left[egin{array}{c} x_1 - x_2 \\ 3x_4 - x_3 \\ 2x_1 + x_4 + x_5 \\ dots \end{array}
ight] = oldsymbol{A} oldsymbol{x} \quad ext{ for some } oldsymbol{A} \in \mathbb{R}^{\mathsf{M} imes \mathsf{D}}$$

No, it basically does nothing since

$$\min_{\boldsymbol{w} \in \mathbb{R}^{\mathsf{M}}} \sum_{n} \left( \boldsymbol{w}^{\mathsf{T}} \boldsymbol{A} \boldsymbol{x}_{n} - y_{n} \right)^{2} = \min_{\boldsymbol{w'} \in \mathsf{Im}(\boldsymbol{A}^{\mathsf{T}}) \subset \mathbb{R}^{\mathsf{D}}} \sum_{n} \left( \boldsymbol{w'}^{\mathsf{T}} \boldsymbol{x}_{n} - y_{n} \right)^{2}$$

We will see more nonlinear mappings soon.

#### Outline

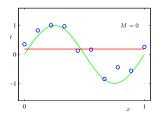

- Review
- 2 Problem Solving
- 3 Linear regression
- 4 Linear regression with nonlinear basis
- **6** Overfitting and Preventing Overfitting
- 6 Problem Solving

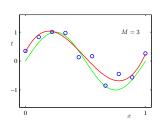

July 6, 2020 46 / 61

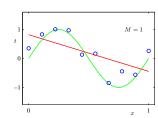

July 6, 2020 45 / 61

### Should we use a very complicated mapping?

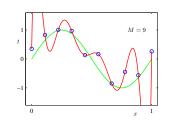

Ex: fitting a sine function with a polynomial:

Training error is zero:

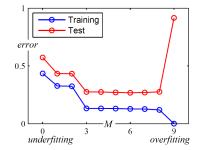

### Underfitting and Overfitting

 $M \leq 2$  is *underfitting* the data

- large training error
- large test error

 $M \geq 9$  is overfitting the data

- small training error
- large test error

More complicated models  $\Rightarrow$  larger gap between training and test error

How to prevent overfitting?

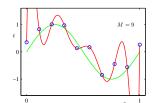

July 6, 2020 47 / 61

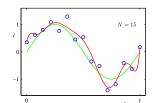

July 6, 2020

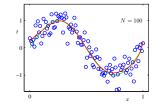

48 /

#### Method 1: use more training data

The more, the merrier. We increase N - the number of training points.

More data ⇒ smaller gap between training and test error

July 6, 2020 49 / 61

#### How to make w small?

Regularized linear regression: new objective

$$\mathcal{E}(\boldsymbol{w}) = \text{RSS}(\boldsymbol{w}) + \lambda R(\boldsymbol{w})$$

Goal: find  $w^* = \operatorname{argmin}_w \mathcal{E}(w)$ 

- $R: \mathbb{R}^{\mathsf{D}} \to \mathbb{R}^+$  is the *regularizer* 
  - lacktriangleright measure how complex the model w is
  - ightharpoonup common choices:  $\|\boldsymbol{w}\|_2^2$  (ridge),  $\|\boldsymbol{w}\|_1$  (lasso), etc.
- $\lambda > 0$  is the *regularization coefficient* 
  - $\lambda = 0$ , no regularization
  - $\qquad \qquad \boldsymbol{\lambda} \to +\infty, \ \boldsymbol{w} \to \operatorname{argmin}_w R(\boldsymbol{w})$
  - ▶ i.e. control **trade-off** between training error and complexity

#### Method 2: control the model complexity

For polynomial basis, the **degree** M controls the complexity

	M = 0	M = 1	M = 3	M = 9
$\overline{w_0}$	0.19	0.82	0.31	0.35
$w_1$		-1.27	7.99	232.37
$w_2$			-25.43	-5321.83
$w_3$			17.37	48568.31
$w_4$				-231639.30
$w_5$				640042.26
$w_6$				-1061800.52
$w_7$				1042400.18
$w_8$				-557682.99
$w_9$				125201.43

Intuitively, *large weights* ⇒ *more complex model* 

Use cross-validation to pick hyperparameter  ${\cal M}$ 

Are there still other ways to control complexity?

July 6, 2020 50 /

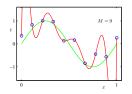

#### The effect of $\lambda$

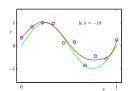

#### when we increase regularization coefficient $\boldsymbol{\lambda}$

	$\ln \lambda = -\infty$	$\ln \lambda = -18$	$\ln \lambda = 0$
	$m_A = -\infty$	$m_A = -10$	$m_A = 0$
$w_0$	0.35	0.35	0.13
$w_1$	232.37	4.74	-0.05
$w_2$	-5321.83	-0.77	-0.06
$w_3$	48568.31	-31.97	-0.06
$w_4$	-231639.30	-3.89	-0.03
$w_5$	640042.26	55.28	-0.02
$w_6$	-1061800.52	41.32	-0.01
$w_7$	1042400.18	-45.95	-0.00
$w_8$	-557682.99	-91.53	0.00
$w_9$	125201.43	72.68	0.01

#### The trade-off

When we increase regularization coefficient  $\lambda$ , overfitting decreases:

# How to choose the right amount of regularization?

Can we tune  $\lambda$  on the training dataset?

*No*: as this will set  $\lambda$  to zero, i.e., without regularization, defeating our intention to use it to control model complexity and to gain better generalization.

 $\lambda$  is a hyperparameter. To tune it,

- We can use a development/holdout dataset independent of training and testing dataset.
- We can use cross-validation.

The procedure is similar to choose K in the nearest neighbor classifiers.

#### The root of overfitting

Dealing with over and underfitting is really about dealing with bias and variance.

Mathematically, the expected prediction error can be decomposed into bias and variance components.

Simpler models have a smaller variance but a larger bias.

Complex models have a larger variance but a smaller bias.

Thus, we balance bias and variance by choosing  $\lambda$ .

Regularization reduces variance (because they lead to simpler models) but then increase the bias.

### How to solve the new objective?

Simple for  $R(\boldsymbol{w}) = \|\boldsymbol{w}\|_2^2$ :

$$\mathcal{E}(\boldsymbol{w}) = \text{RSS}(\boldsymbol{w}) + \lambda \|\boldsymbol{w}\|_{2}^{2} = \|\boldsymbol{\Phi}\boldsymbol{w} - \boldsymbol{y}\|_{2}^{2} + \lambda \|\boldsymbol{w}\|_{2}^{2}$$
$$\nabla \mathcal{E}(\boldsymbol{w}) = 2(\boldsymbol{\Phi}^{T}\boldsymbol{\Phi}\boldsymbol{w} - \boldsymbol{\Phi}^{T}\boldsymbol{y}) + 2\lambda \boldsymbol{w} = 0$$
$$\Rightarrow (\boldsymbol{\Phi}^{T}\boldsymbol{\Phi} + \lambda \boldsymbol{I}) \boldsymbol{w} = \boldsymbol{\Phi}^{T}\boldsymbol{y}$$
$$\Rightarrow \boldsymbol{w}^{*} = (\boldsymbol{\Phi}^{T}\boldsymbol{\Phi} + \lambda \boldsymbol{I})^{-1} \boldsymbol{\Phi}^{T}\boldsymbol{y}$$

Note the same form as in the fix when  $X^TX$  is not invertible!

For other regularizers, as long as it's **convex**, standard optimization algorithms can be applied.

### Equivalent form

Regularization is also sometimes formulated as

$$\underset{\boldsymbol{w}}{\operatorname{argmin}} \operatorname{RSS}(w) \quad \text{ subject to } R(\boldsymbol{w}) \leq \beta$$

where  $\beta$  is some hyperparameter.

Finding the solution becomes a *constrained optimization problem*.

Choosing either  $\lambda$  or  $\beta$  can be done by cross-validation.

### Summary

Linear regression summarized:

$$egin{aligned} oldsymbol{w}^* &= \left( oldsymbol{X}^{\mathrm{T}} oldsymbol{X} 
ight)^{-1} oldsymbol{X}^{\mathrm{T}} oldsymbol{y} \ oldsymbol{w}^* &= \left( oldsymbol{A}^{\mathrm{T}} oldsymbol{A} + \lambda oldsymbol{I} 
ight)^{-1} oldsymbol{\Phi}^{\mathrm{T}} oldsymbol{y} \ oldsymbol{w}^* &= \left( oldsymbol{\Phi}^{\mathrm{T}} oldsymbol{\Phi} + \lambda oldsymbol{I} 
ight)^{-1} oldsymbol{\Phi}^{\mathrm{T}} oldsymbol{y} \end{aligned}$$

It is important to understand the derivation.

**Overfitting**: small training error but large test error.

**Preventing Overfitting**: more data and/or regularization.

### Typical steps

Typical steps of developing a machine learning system:

- Collect data, split into training, development, and test sets.
- Train an ML model with training data to learn from.
- Evaluate it using the test data and report performance.
- Use the model to predict future/make decisions.

How to do the *red part* exactly?

### General idea to provide ML algorithms

- 1. Pick a set of models  $\mathcal{F}$ 
  - $\bullet$  e.g.  $\mathcal{F} = \{ f(x) = w^{\mathrm{T}}x \mid w \in \mathbb{R}^{\mathrm{D}} \}$
  - ullet e.g.  $\mathcal{F} = \{f(oldsymbol{x}) = oldsymbol{w}^{\mathrm{T}} oldsymbol{\Phi}(oldsymbol{x}) \mid oldsymbol{w} \in \mathbb{R}^{\mathsf{M}} \}$
- 2. Define **error/loss** L(y', y)
- 3. Find empirical risk minimizer (ERM):

$$f^* = \underset{f \in \mathcal{F}}{\operatorname{argmin}} \sum_{n=1}^{N} L(f(x_n), y_n)$$

or regularized empirical risk minimizer:

$$f^* = \underset{f \in \mathcal{F}}{\operatorname{argmin}} \sum_{n=1}^{N} L(f(x_n), y_n) + \lambda R(f)$$

ML becomes optimization

# Solution

### Problem 1

Minimize the total absolute error  $(L_1 \text{ norm})$  of linear regression when D = 0:

$$\min_{w_0} \sum_n |w_0 - y_n|$$

### Problem 2

Suppose A is a square matrix. Then A is singular if and only if  $\lambda = 0$  is an eigenvalue of A. Prove this statement.

## Problem 3

Suppose A is a square nonsingular matrix and  $\lambda$  is an eigenvalue of A. Prove that  $1/\lambda$  is an eigenvalue of the matrix  $A^{-1}$ .

### Problem 4

Find eigenvalues and eigenvectors for

$$A = \begin{pmatrix} 2 & 3 \\ 2 & 1 \end{pmatrix}$$

Find an eigendecomposition for A.

### Solution

### Problem 5

The eigenvectors of a symmetric matrix A corresponding to different eigenvalues are orthogonal to each other. Prove this statement.

## Problem 6

Every positive semidefinite matrix has eigenvalues  $\geq 0$ 

## Solution

# Problem 7

Let u,  $x \in \mathbb{R}^n$  are column vectors, A is (nxn) matrix.

Task 1. Compute 
$$\frac{\partial}{\partial x}u^{\mathrm{T}}x$$
 and  $\frac{\partial}{\partial x}x^{\mathrm{T}}u$ 

Task 2. Compute 
$$\frac{\partial}{\partial x} \|x\|_2^2$$

Task 3. Compute 
$$\frac{\partial}{\partial x} x^{\mathrm{T}} A x$$
